# Cloud Computing

*"Cloud computing is a model for enabling ubiquitous, convenient, on-demand network access to a shared pool of configurable computing resources (e.g., networks, servers, storage, applications, and services) that can be rapidly provisioned and released with minimal management effort or service provider interaction. "*

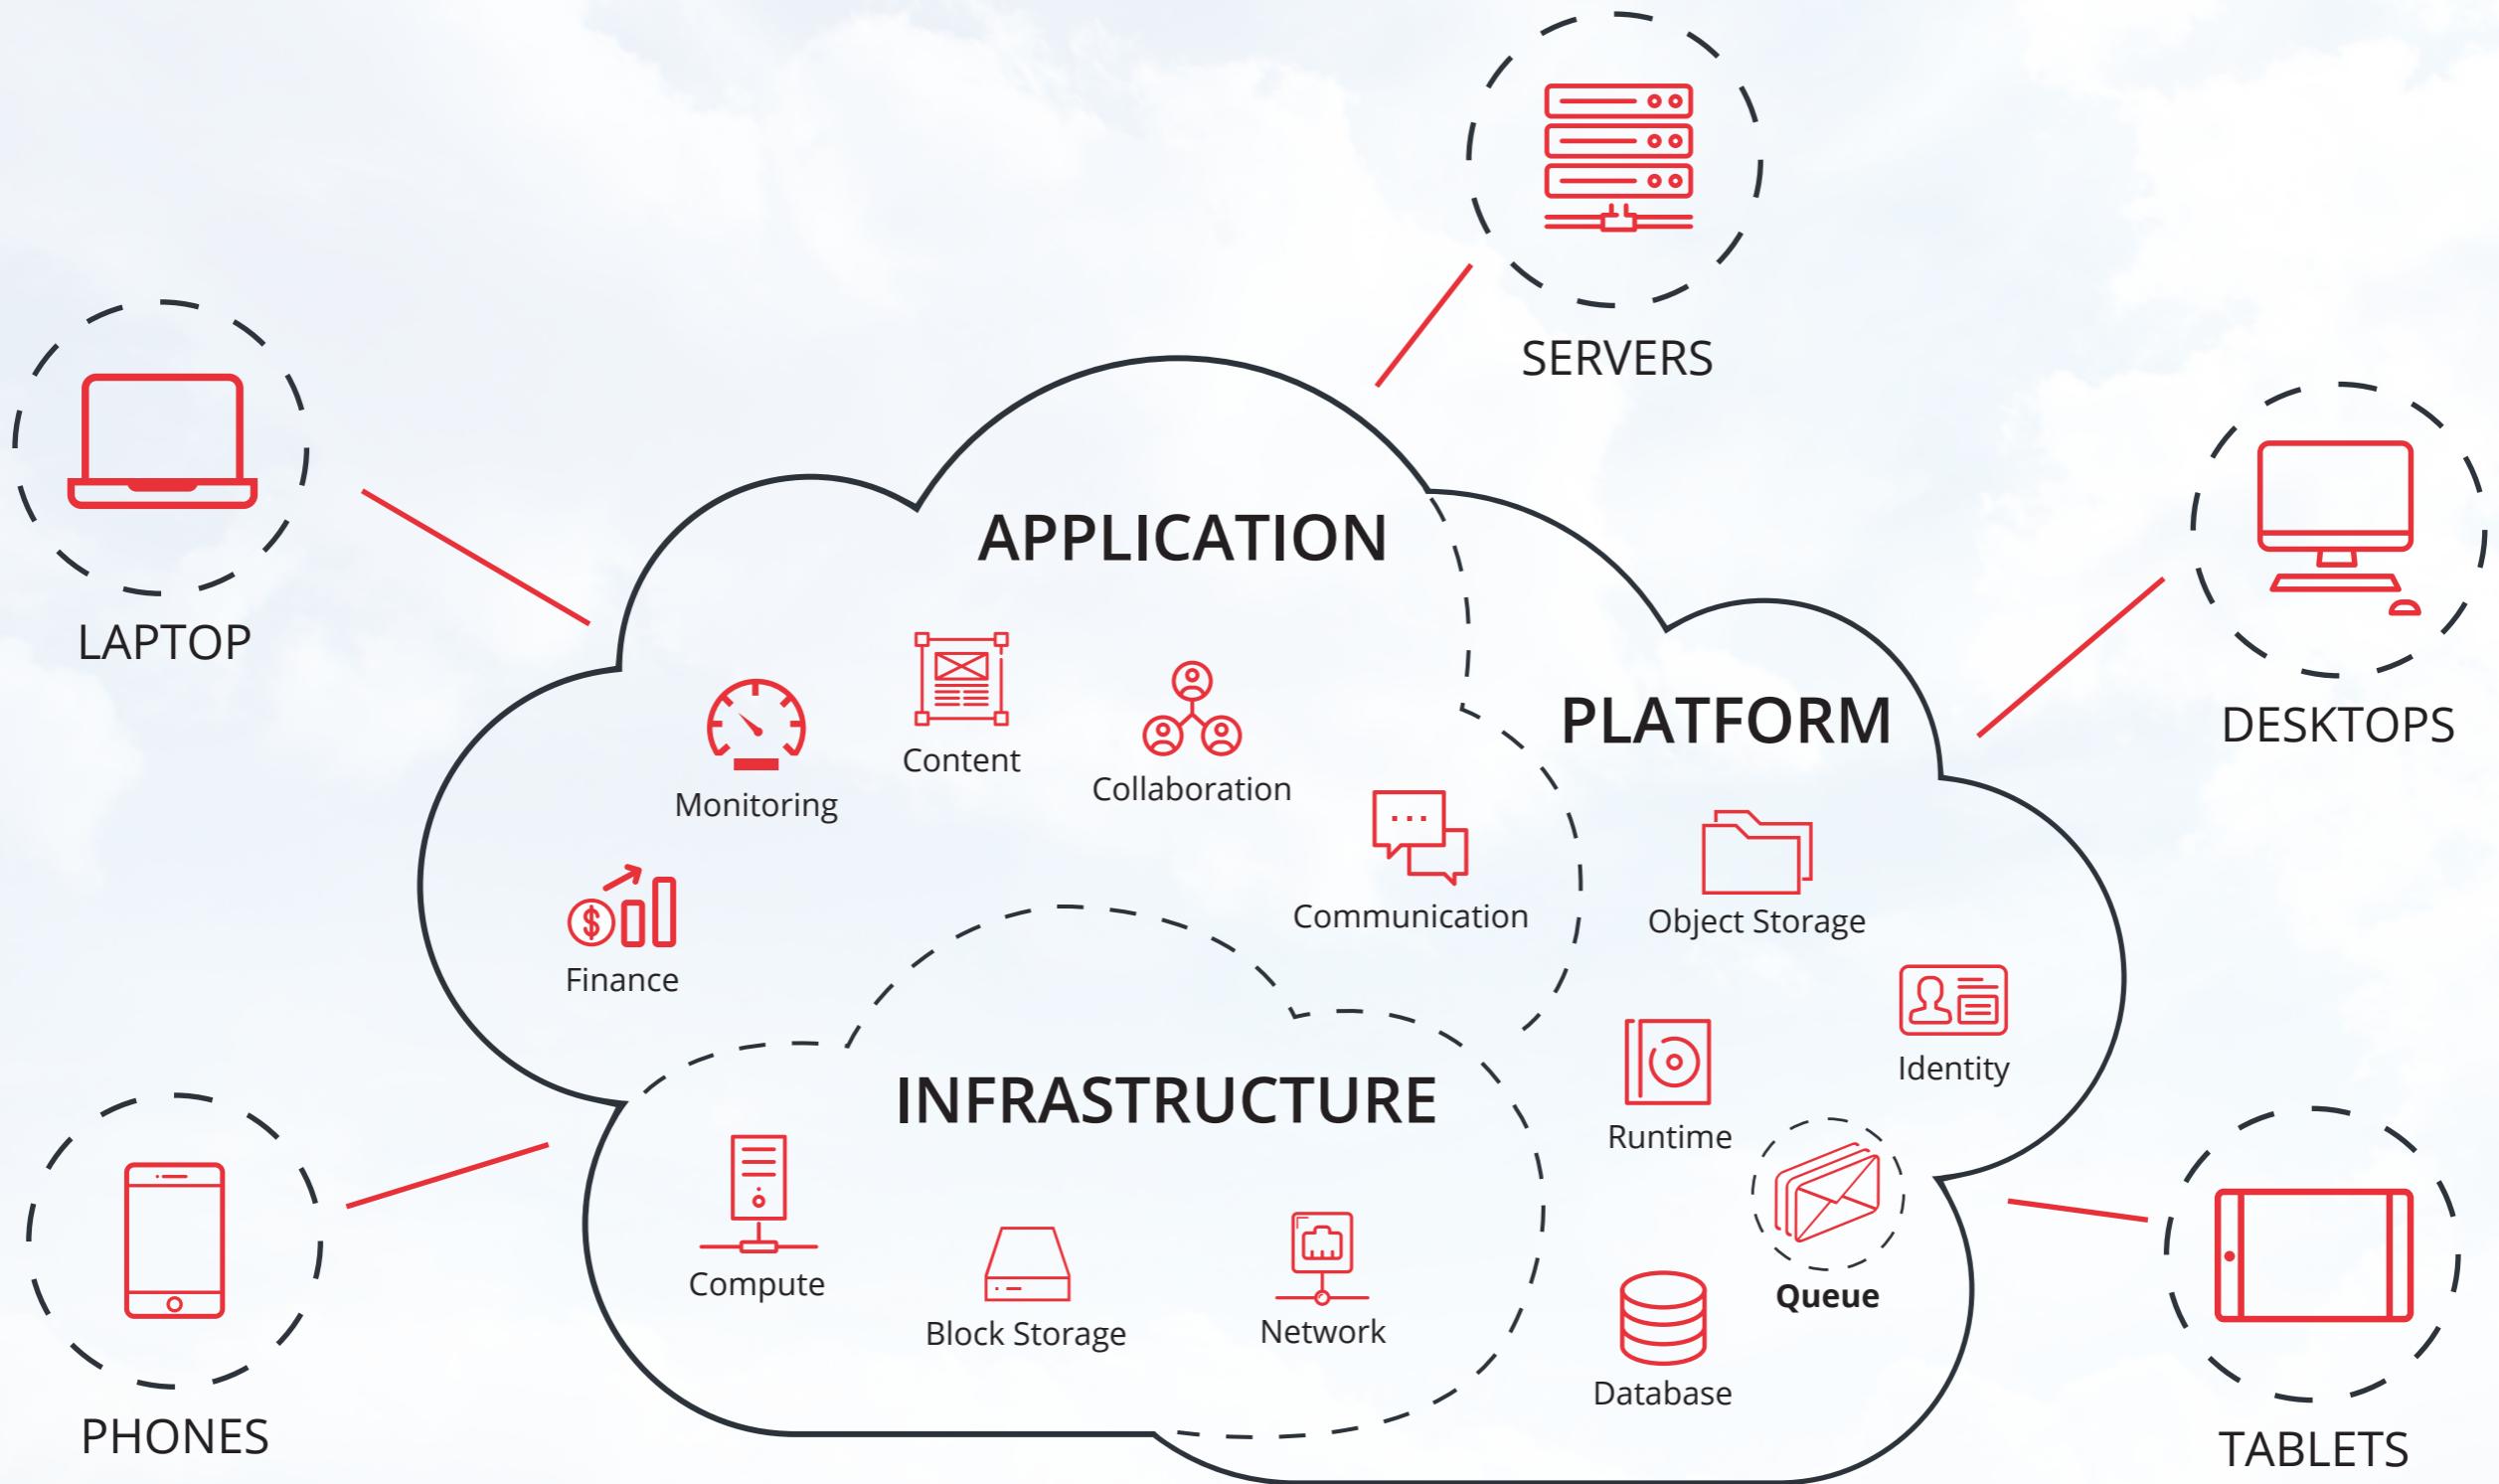

**The NIST Definition of Cloud Computing**

# Cloud Computing Layers

# Characteristics

<http://dx.doi.org/10.6028/NIST.SP.800-145>

## On-demand self-service

A consumer can unilaterally provision computing capabilities, such as server time and network storage, as needed automatically without requiring human interaction with each service provider.

## Broad network access

Capabilities are available over the network and accessed through standard mechanisms that promote use by heterogeneous thin or thick client platforms (e.g., mobile phones, tablets, laptops, and workstations).

## Resource pooling

The provider's computing resources are pooled to serve multiple consumers using a multi-tenant model, with different physical and virtual resources dynamically assigned and reassigned according to consumer demand. There is a sense of location independence in that the customer generally has no control or knowledge over the exact location of the provided resources but may be able to specify location at a higher level of abstraction (e.g., country, state, or datacenter). Examples of resources include storage, processing, memory, and network bandwidth.

## Rapid elasticity

Capabilities can be elastically provisioned and released, in some cases automatically, to scale rapidly outward and inward commensurate with demand. To the consumer, the capabilities available for provisioning often appear to be unlimited and can be appropriated in any quantity at any time.

## Measured service

Cloud systems automatically control and optimize resource use by leveraging a metering capability at some level of abstraction appropriate to the type of service (e.g., storage, processing, bandwidth, and active user accounts). Resource usage can be monitored, controlled, and reported, providing transparency for both the provider and consumer of the utilized service.

# Apache Karaf

Vancouver 2016

# Karaf - Features

- › **Hot deployment:** simply drop a file in the deploy directory
- › **Complete Console:** complete Unix-like console for managing the container.
- › **Dynamic Configuration:** extensible set of commands focused on managing configuration.
- › **Advanced Logging System:** supports all the popular logging frameworks (slf4j, log4j, etc)
- › **Provisioning:** supports a large set of URLs where you can install your applications, plus 'features' and 'profiles'
- › **Management:** enterprise-ready container, providing management metrics and operations via JMX.
- › **Remote:** embeds an SSHd server for remote operations.
- › **Security:** complete security framework (based on JAAS) and RBAC (Role-Based Access Control) mechanism
- › **Instances:** multiple instances managed directly from a main instance (root).  
OSGi frameworks: Apache Felix Framework or Equinox

# Karaf Decanter - Overview

## Default implementation based on ELK

### > Collectors

Responsible for harvesting monitoring data.

Two kinds:

*Event Drive Collectors*

*Polling Collectors*

### > Appenders

Receive data from the collectors

Responsible to store data in a given backend

### > Service Level Agreements

Special kind of Appender

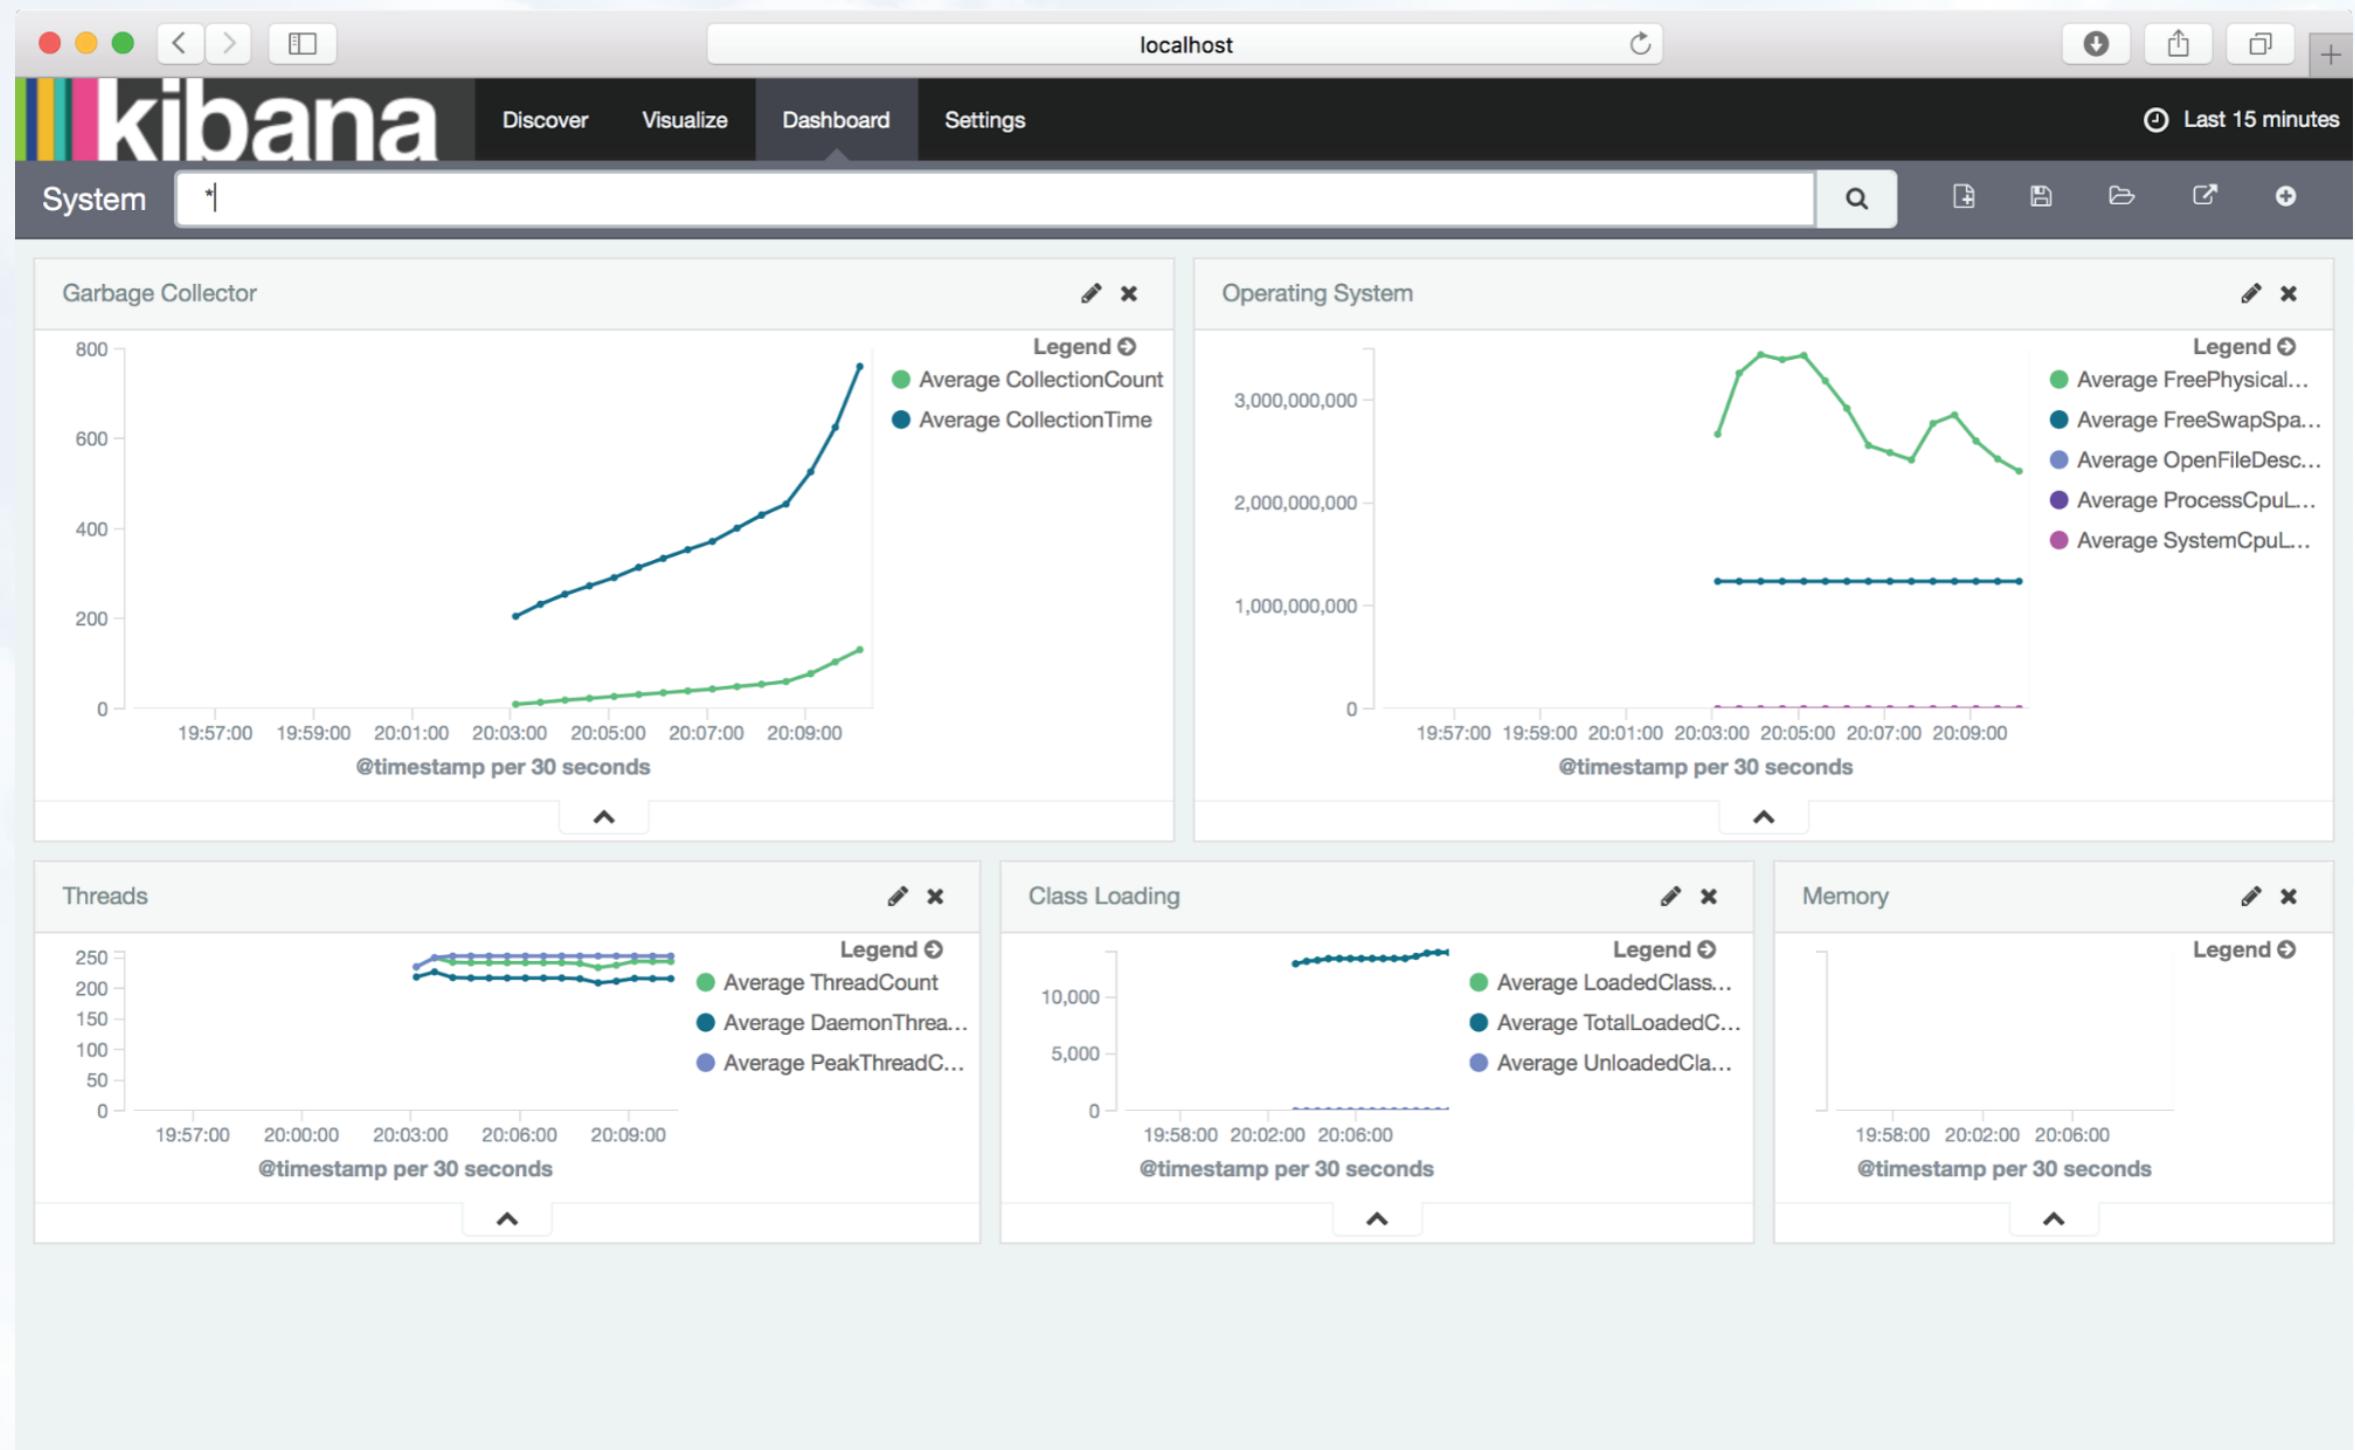

Receives harvested data and performs checks upon it.

*if check fails, alert event is created and sent to alerters.*

# Karaf Decanter - Monitoring

DEMO

SILKMQ

Vancouver 2016

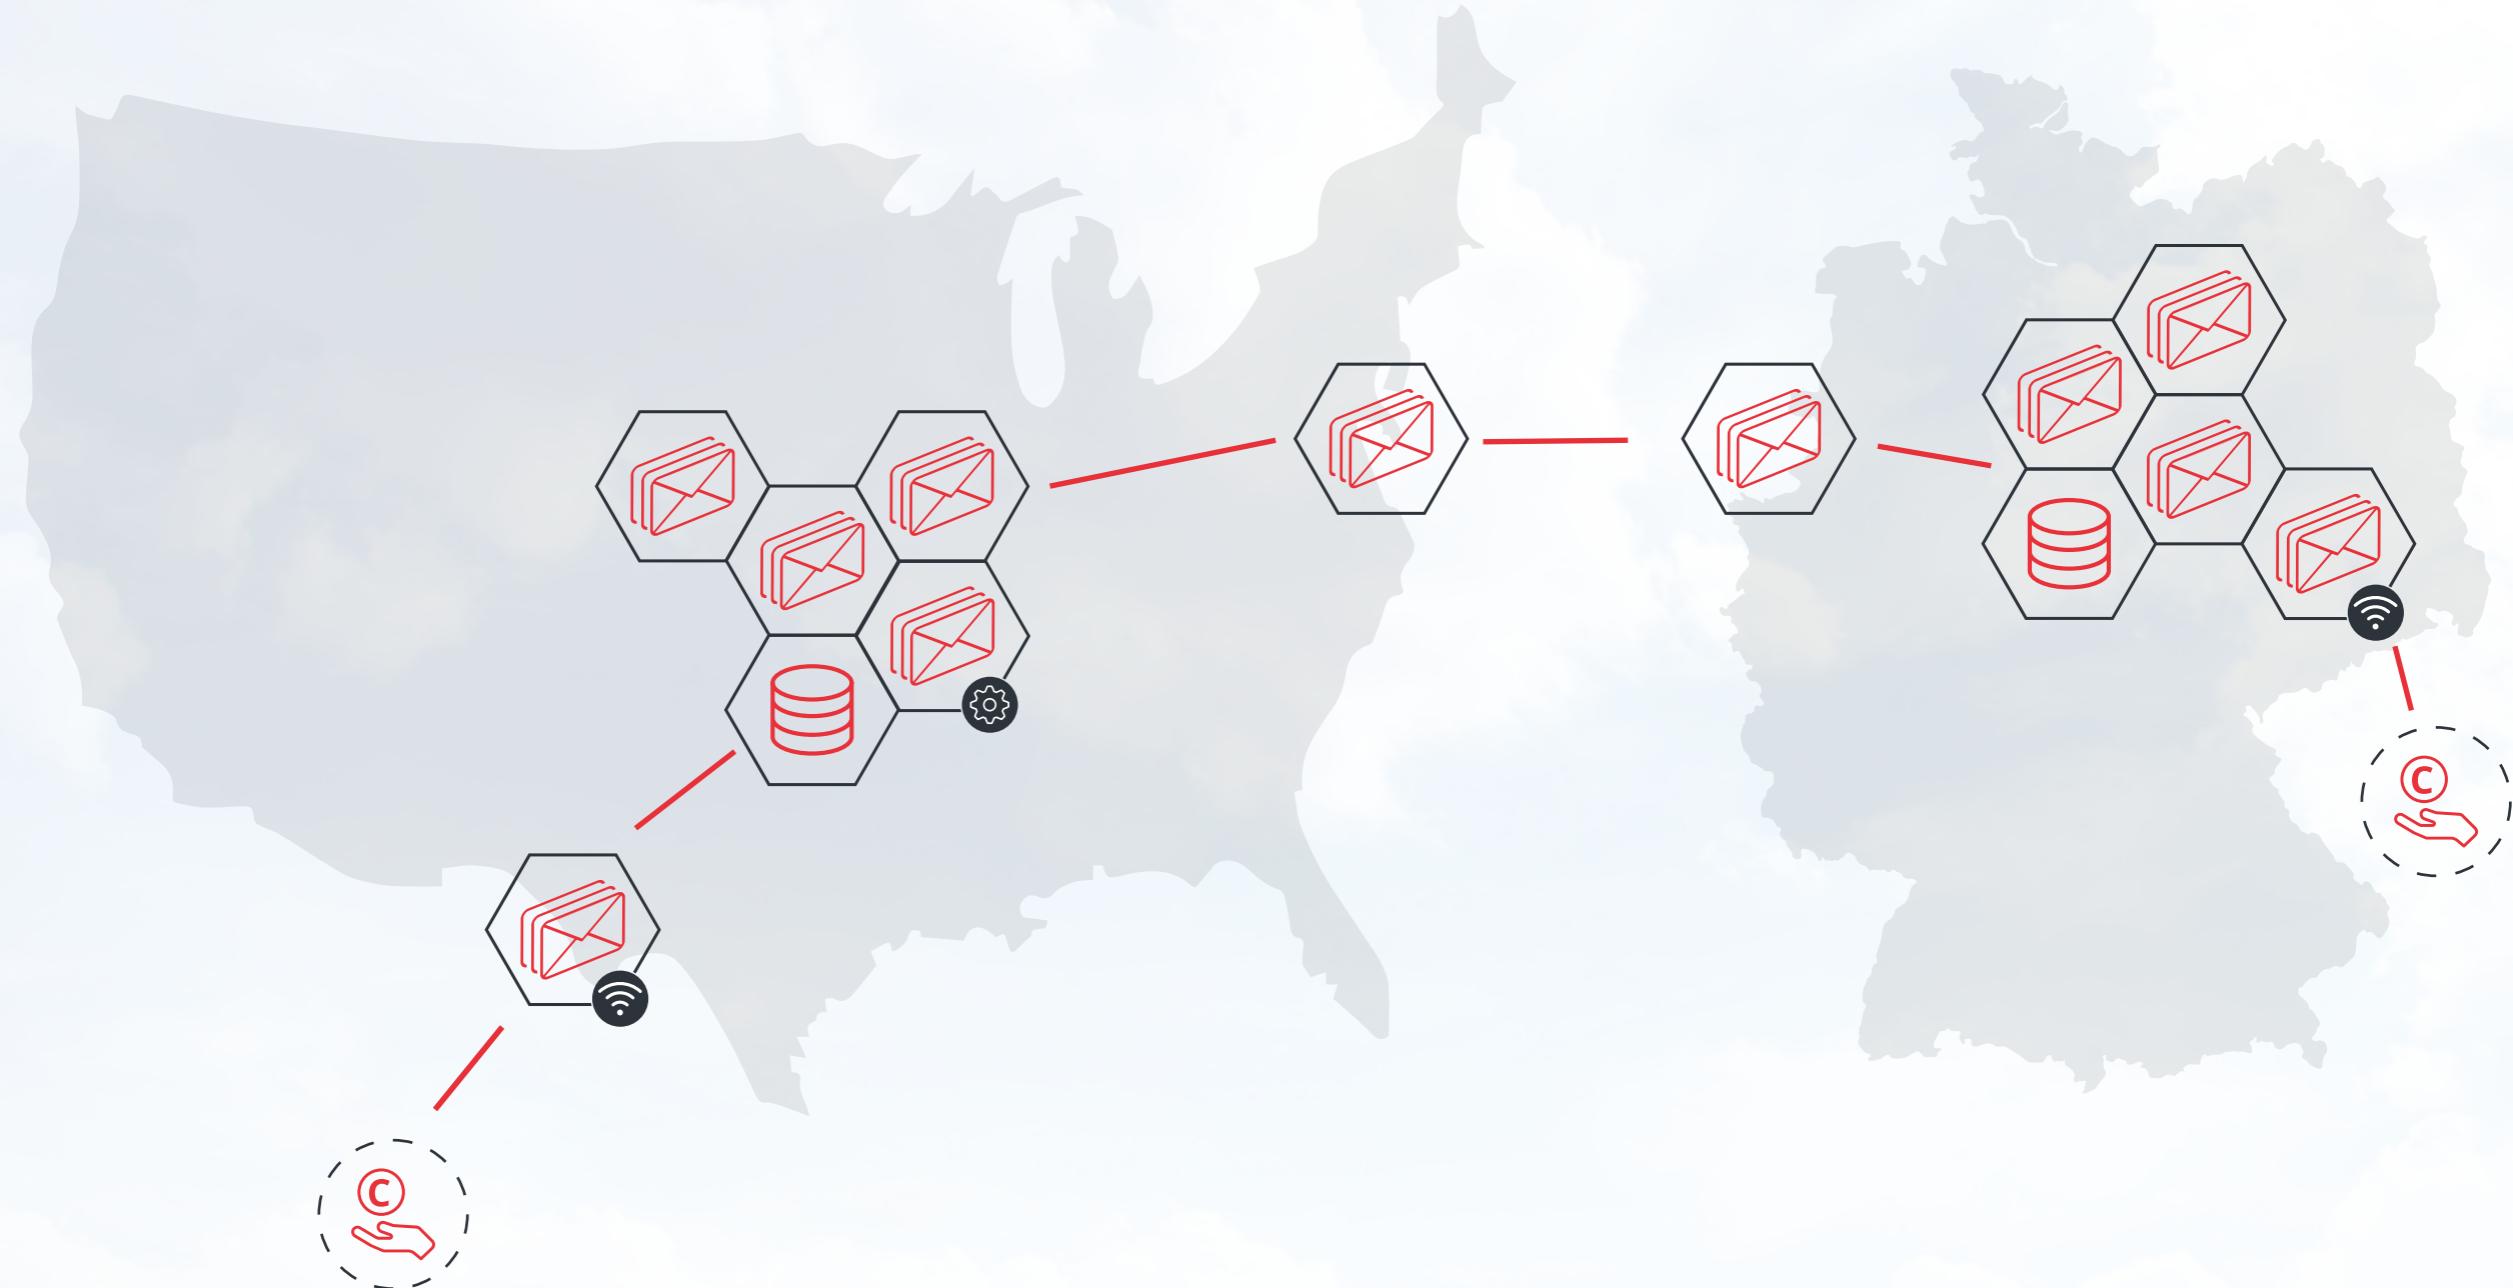

# SilkMQ - What's in a name?

# SilkMQ - Topology

# SilkMQ - Broker Monitoring

**SilkMQ is smooth, shouldn't monitoring be too?**

- › We want Decanter Monitoring to be elastic like SilkMQ
- › Currently Decanter is focussed on individual services
  - Needs more work...
- › We want to view message infrastructure at a higher level
  - How many messages enqueued and dequeued for a project?
  - Status of pending messages
  - SLA: What is the throughput and latency for queue XYZ (in a project)?
- › Tenants are not aware of the physical deployment infrastructure
  - ...nor should they be

## SilkMQ - Broker Management

- › Use metrics and policies to scale elastically
- › Use a service orchestrator

# SilkMQ - Broker Discovery

*"ActiveMQ uses an abstraction called a Discovery Agent to detect remote services such as remote brokers. We can use discovery for JMS clients to auto-detect a Message Broker to connect to, or to provide Networks of Brokers"*

## Multi-step resolution process

- › Host resolution DNS
- › Pluggable resolution logic
  - Multicast, zeroconf, SilkMQ

# SilkMQ - Multi-tenancy

Model based on users/organizations/teams as commonly seen with Cloud Services

# SilkMQ - Demo
